

RPAS a digitální fotogrammetrie jako nástroj pro hodnocení břehové eroze

Jakub Miřijovský

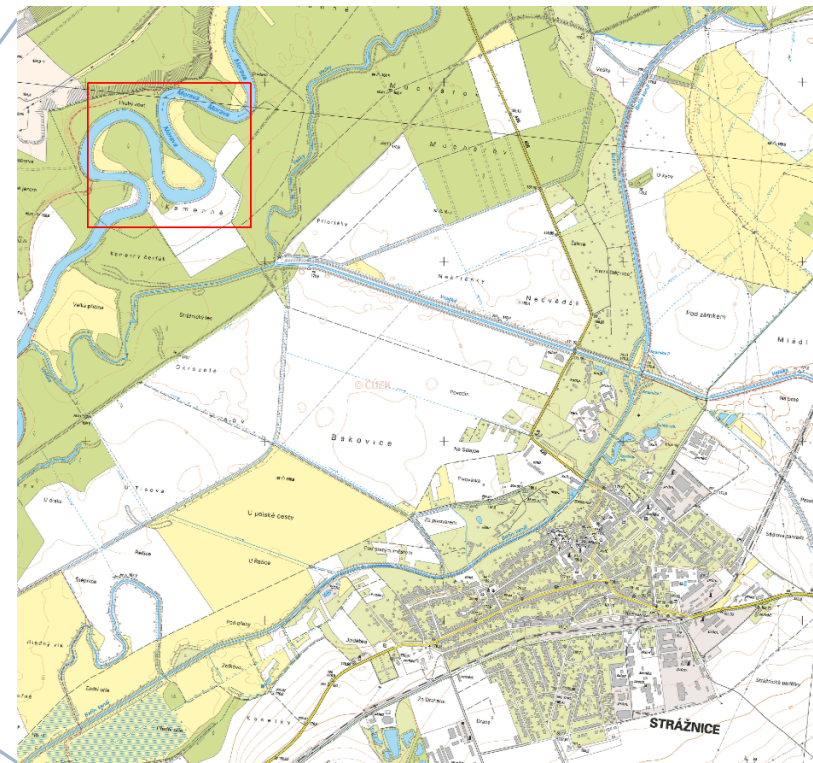

Palacký University Olomouc
Department of Geoinformatics

Short description

- Main aim is: Detailed aerial and terrestrial mapping and flood impact monitoring in the Morava River region (Litovelské Pomoraví Protected area, Osypané Břehy)
- Main target area are lowland regions and region of floodplains near active rivers.

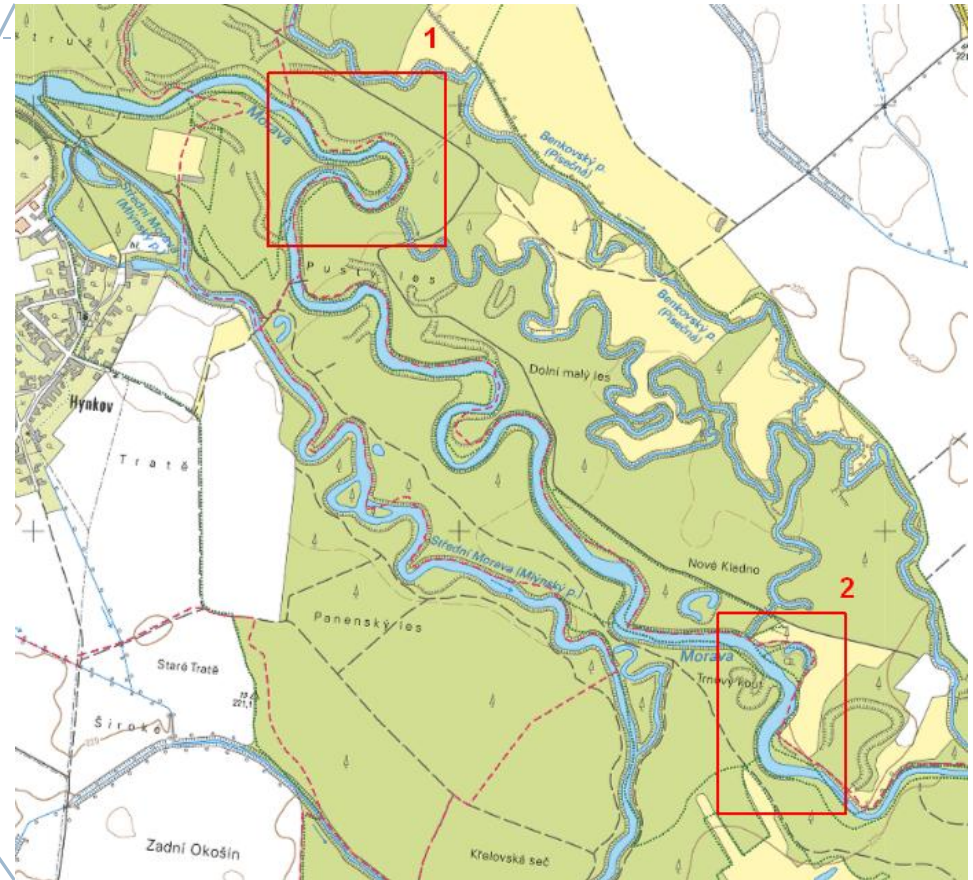

Source: Český úřad zeměměřický a katastrální

1. Meander in the Osypané břehy locality

Area of interest

Source: Český úřad zeměměřický a katastrální

1. Kenický meander
2. river bank with lateral erosion

Floodplain lake

- A floodplain lake is an area of fluvial hydrosystem spatial delimited by an axis of ancient active channel.
- It is composed from two parts: humid perfluvial (aquatic perfluvial zone with ecoton zone) and terestric zone presented by an alluvial plug (Rollet, Citterio, Piégay, 2004).

Floodplain lake

- Floodplain lake is most of the year without water

Methodology

- From methodological point of view, we use the methodology of sediment survey established recently by Citterio & Piégay, 2008.
 - Two steps are considered:
 - The measurement of the sedimentation rates based on the ratio between the mean sediment thickness and the date of the revitalisation;
 - The statistical analysis of the relationships and inter-lake analysis (the characterisation of connection frequency and to define the life expectancy of former channels).
- For a UAV and aerial imaging we use methodology established by Miřijovský, 2013
- Additional measuring
 - Terrestrial photogrammetry
 - Geodetic measuring of the transverse profiles
- Collaboration with Komenského University in Bratislava and Masaryk University in Brno

Dataset

Dataset

Dataset

Technical equipment

- Hexacopter XL, Cessna 172
 - RPAS with six propellers
 - Canon EOS 500D
 - 20 mm lens

- Cessna 172
 - Used to spatially extensive area imaging.

Technical equipment

- Camera, hydrologic and geodetic devices
 - DSLR camera with a prime lens.
 - Rain gauge
 - Levellogger, Barologger
 - Total station Topcon
 - Levelling instrument

Field work

- Installation of the levellogger
- Geodetic measuring – two sets of measuring (cooperation with students of Palacký University).
- Aerial imaging
 - Four flights above the Kenický meander
 - Three flights above the meander in Osypané břehy locality.

Precipitations, water level

- Speed of the lateral erosion and sediments accumulation.

Rain \longrightarrow high water level

- Maximal erosion if there is riverbeds-forming flow

Precipitations, water level

RAW data from an aerial imaging

- Overlay 70 % – 90 %

Very high detail

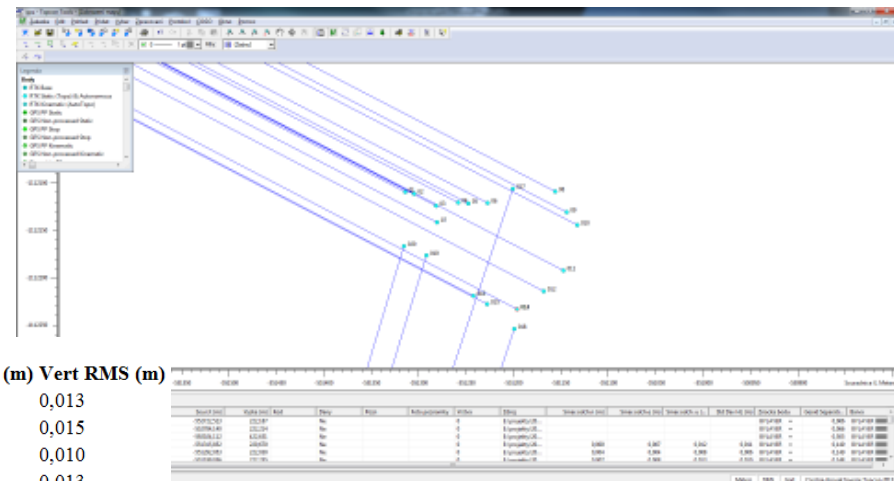

GCPs

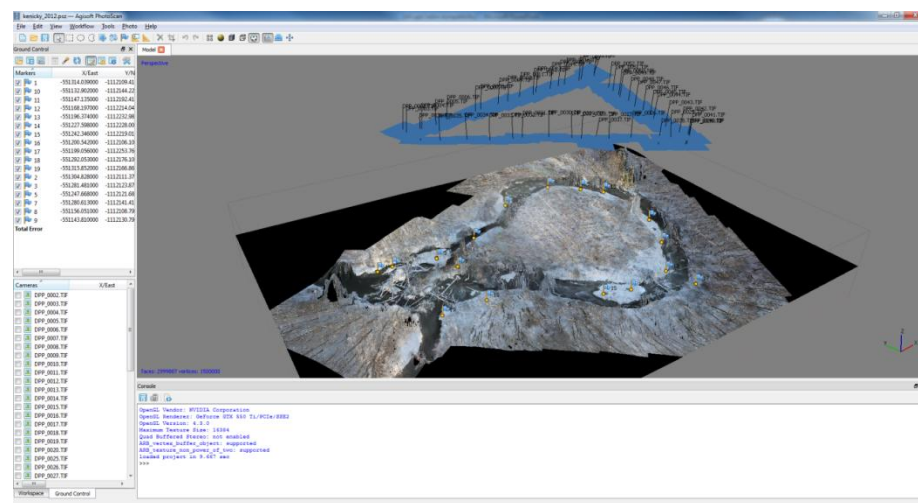

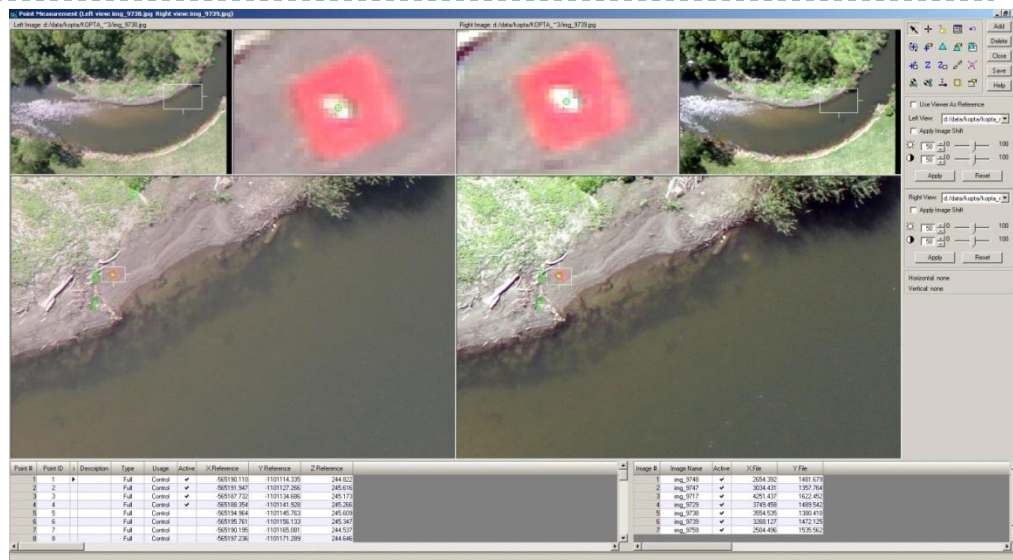

Methods

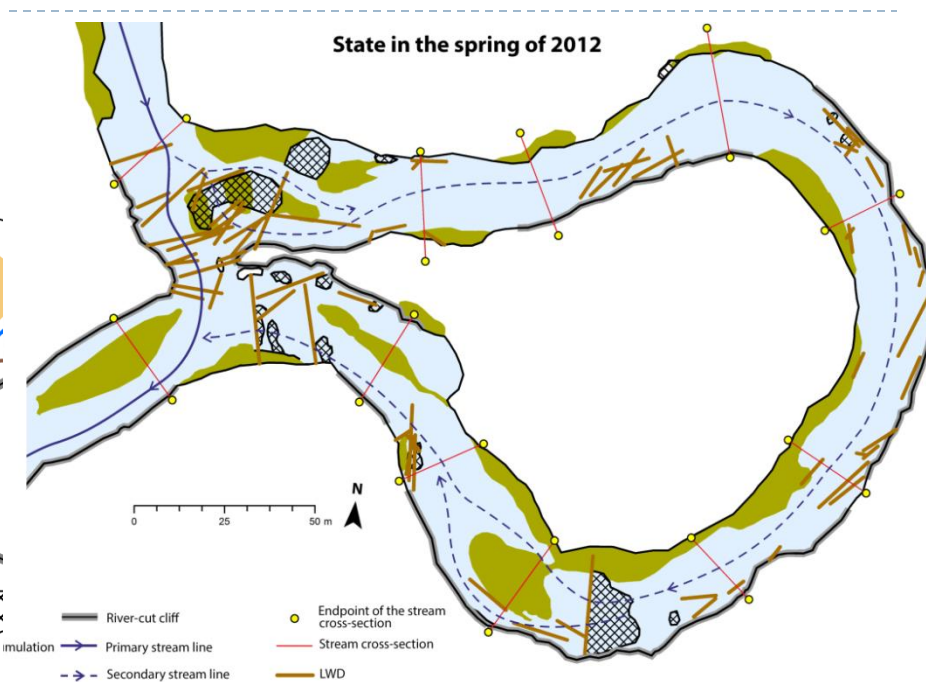

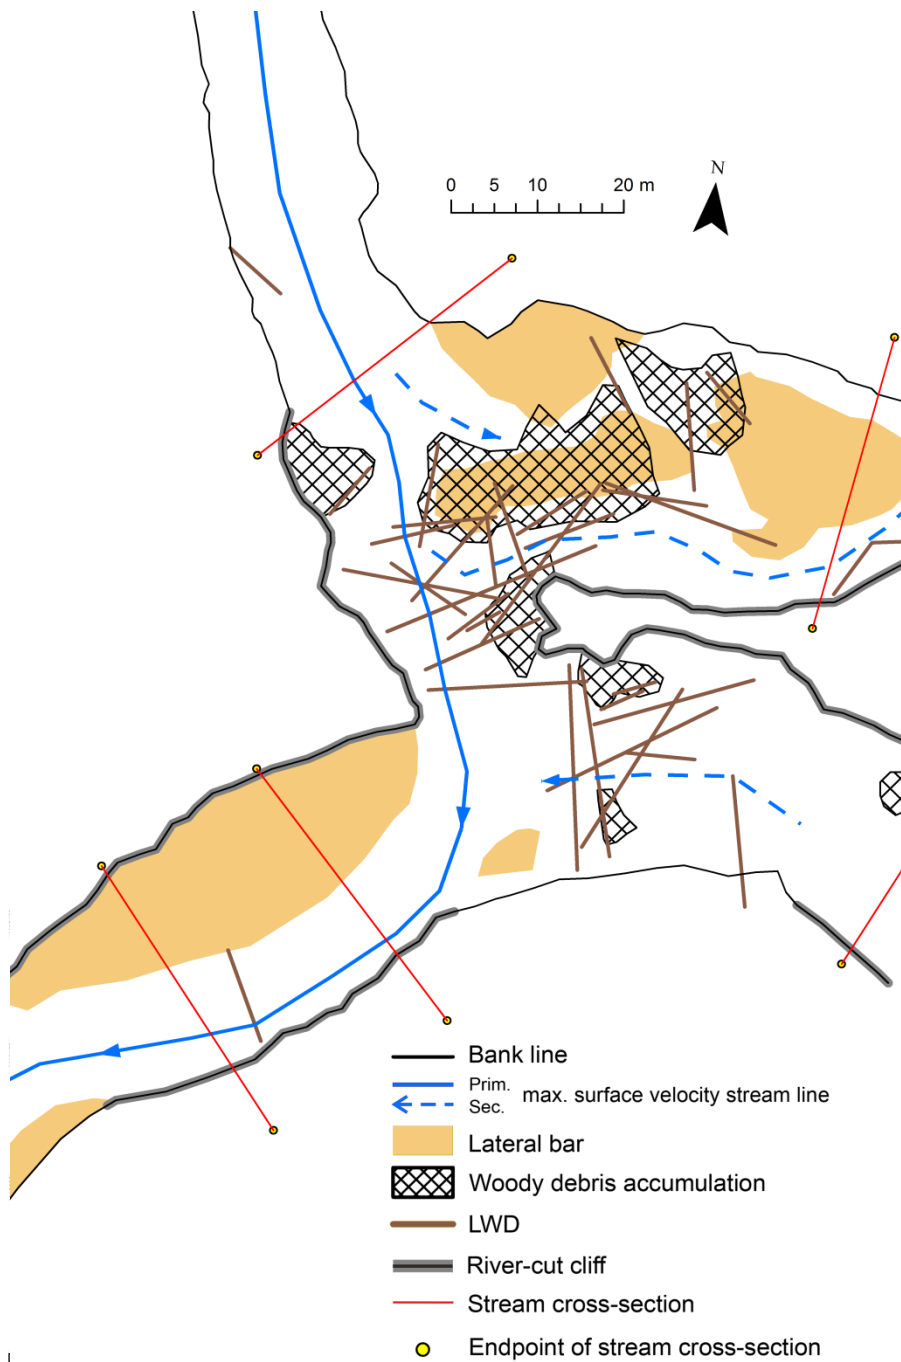

- Interior and Exterior orientation
- Surveying methods
- Very accurate measuring of the Ground Control Points (GCPs), often in a difficult terrain morphology.

Methods

- Photogrammetry processing
 - Structure from Motion
 - Stereophotogrammetry

Results

HYPOTETICAL CHANNEL EVOLUTION OF RIVER MORAVA AFTER NECK CUT-OFF OF KENICKÝ MEADER

Results

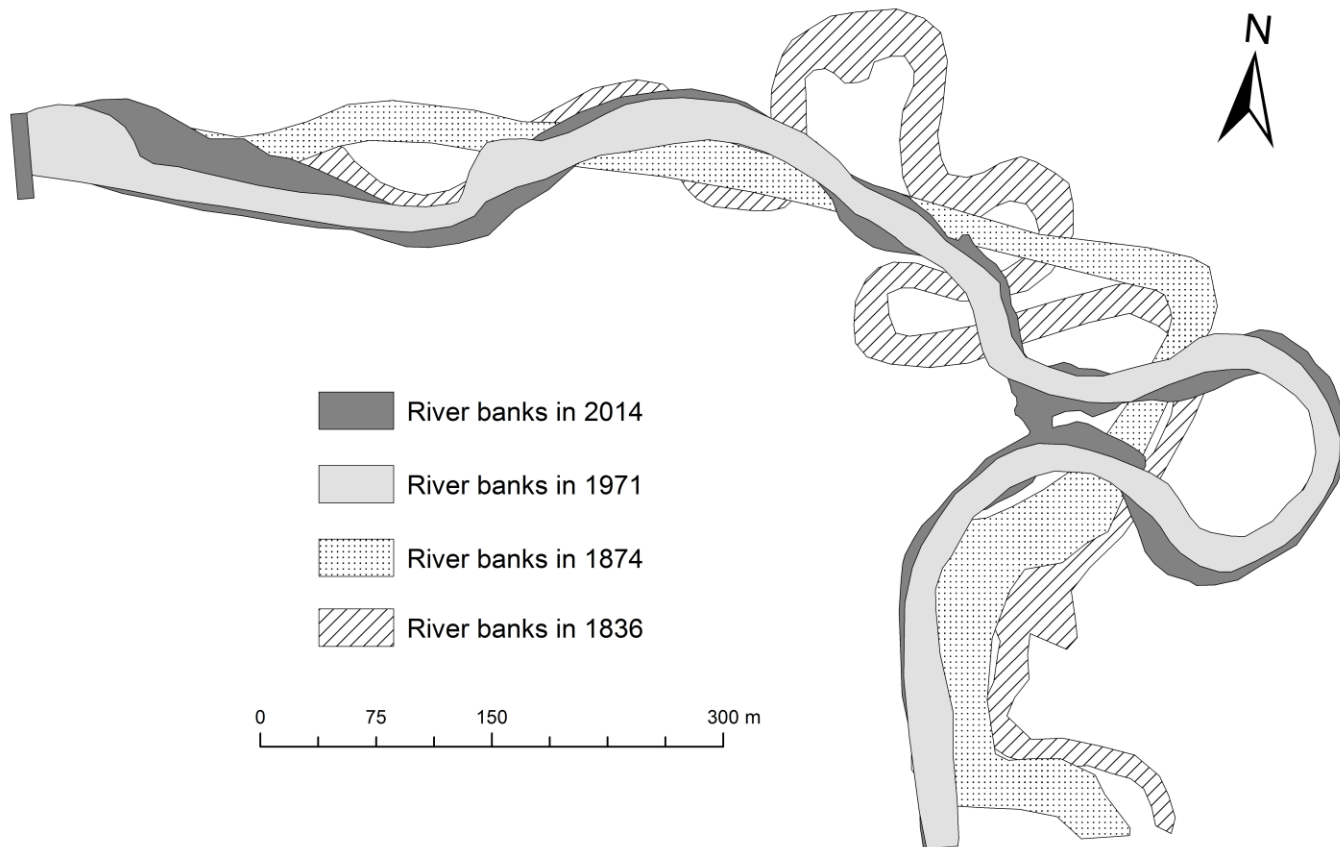

Max. difference: 2 m

Results

The river banks of the Morava river between years 1836 - 2014

Results

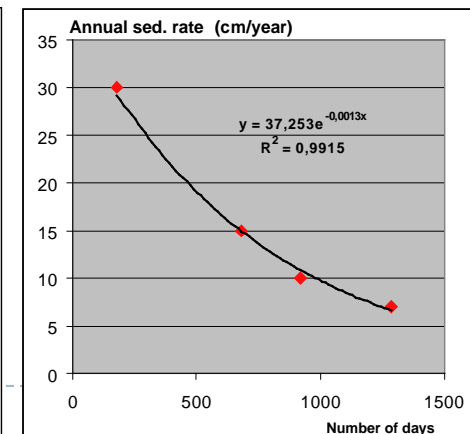

Future work

- Continuation in terrestrial monitoring
 - Hydrological data (precipitations, height of a water level, water flow).
 - Aerial data (RPAS and aerial imaging).
 - Terrestrial measuring (transverse profiles)

- Obtaining of a new data
 - Data for granulometry

- Modeling
 - prediction of sedimentation. It is a function of overflowing discharge upstream and downstream
